Lecture 26: Key Questions November 14, 2016

1. (Review) Describe how to operate on multi-byte data.

- 2. Translate these x86 operations to PIC code. Assume that there are registers defined for each x86 register (e.g. AL, AH, BL, BH, etc.). 16-bit values (e.g., AX) must be dealt with as individual bytes
- MOVZX AX, BL

• MOVSX AX, BL

• INC AX

- 2. (continued) Translate these x86 operations to PIC code. Assume that there are registers defined for each x86 register (e.g. AL, AH, BL, BH, etc.). 16-bit values (e.g., AX) must be dealt with as individual bytes
- SUB BX, AX

• RCL AX, 5

Describe the operation of the given subroutine, which implements a 10 ms delay loop. Questions related to this loop are on the following page of the handout.

; TenMs subroutine and its call inserts a delay of exactly ten milliseconds

; into the execution of code.

; It assumes a 4 MHz crystal clock. One instruction cycle = 4 * Tosc.

; TenMsH equ 13 ; Initial value of TenMs Subroutine's counter

; TenMsL equ 250

```
; COUNTH and COUNTL are two variables
```

TenMs

| | nop | | ; one cycle | | |
|-------|--------|----------|--------------------|--|--|
| | movlw | TenMsH | ; Initialize COUNT | | |
| | movwf | COUNTH | | | |
| | movlw | TenMsL | | | |
| | movwf | COUNTL | | | |
| Ten 1 | | | | | |
| _ | decfsz | COUNTL,F | ; Inner loop | | |
| | goto | Ten 1 | • | | |
| | decfsz | COUNTH,F | : Outer loop | | |
| | goto | Ten 1 | , - - | | |
| | return | | | | |
| | | | | | |

1. What factors determine the amount of delay in this loop?

2. What's the downside of using a loop for delay?

3. Under what conditions does this function decrement COUNTH?

4. Under what conditions does this function return?

5. How many times does each instruction in this function execute?

Describe the operation of the given subroutine, which toggles a series of 3 LEDs in sequence, assuming those LEDs are attached to bits 0-2 of Port D. Questions related to this function start on the next page of the handout.

BlinkTable

| movf | PORTD, W | ; Copy present state of LEDs into W |
|-------|-------------|-----------------------------------------|
| andlw | B'00000111' | ; and keep only LED bits |
| addwf | PCL,F | ; Change PC with PCLATH and offset in W |
| retlw | B'00000001' | ; (000 -> 001) reinitialize to green |
| retlw | B'00000011' | ; (001 -> 010) green to yellow |
| retlw | B'00000110' | ; (010 -> 100) yellow to red |
| retlw | B'00000010' | ; (011 -> 001) reinitialize to green |
| retlw | B'00000101' | ; (100 -> 001) red to green |
| retlw | B'00000100' | ; (101 -> 001) reinitialize to green |
| retlw | B'00000111' | ; (110 -> 001) reinitialize to green |
| retlw | B'00000110' | ; (111 -> 001) reinitialize to green |
| | | |

In calling program

| call | BlinkTable | ; get bits to change into W |
|-------|------------|-----------------------------|
| xorwf | PORTD, F | ; toggle them into PORTD |

6. What do the first two instructions in this function do?

7. What does the **addwf** instruction do?

8. Why do we need 8 retlw instructions?

9. How is each return value used?

10. Why are the upper 5 bits of every return value equal to 0?
